13 14 **Abstract**

15 Foodborne diseases are of major concern for public health. Here we assess the
16 microbiological quality and safety of marinated pork steaks (n=300) and marinades (n=30)
17 which were used for the production of marinated steaks by analyzing quantitative
18 microbiological parameters and foodborne pathogens. *Salmonella* spp. and *Listeria*
19 *monocytogenes* were isolated from about 2 %, *Staphylococcus aureus* from 8 % and *Bacillus*
20 *cereus* from 21 % of the steaks. One steak was MRSA-positive and one contained
21 EHEC/STEC. *Bacillus cereus* was the only pathogen detected in the marinades. Similar toxin
22 patterns of *B. cereus* strains from meat and marinades suggested that a contamination of
23 meat with *B. cereus* occurred via marinades.

24

26 toxigenicity; pathogen;

27 28 **1. Introduction**

29 Food borne infections are of major concern for public health and cause substantial costs
30 (Hoffmann et al., 2012), despite of reinforced actions by governments and food industry for
31 better food hygiene. Changing lifestyles might contribute to this situation, such as the rise of
32 single-households possibly accompanied by a decreasing knowledge of proper food handling
33 and a growing demand for convenience food (Brunner et al., 2010).

34 Amongst the category of convenience food, pre-packed marinated meat products such as
35 steaks, spare ribs and filets are becoming increasingly popular (O'Donnell, 2004; ZMP, 2007).
36 In Germany, about 400,000 tons of barbecue products from pork, beef and chicken were sold
37 during the barbecue season in 2007. Within this section of meat products, marinated pork
38 neck steaks are the most popular (ZMP, 2007). In Germany, marinated pork neck steaks are
39 produced usually from frozen pork necks with industrial marinade. Minimum shelf life, as
40 assigned by producers, ranges from 13 to 18 days.

41 A small, focused microbiological and sensory study, published by the German consumer's
42 magazine „Stiftung Warentest“ in 2008, indicated in part poor food hygienic quality for
43 marinated, pre-packed meat products (Anon., 2008). Consequently, a possible obscuring of
44 poor hygienic conditions by marinating was discussed in the public. Currently, there are no
45 convincing data about the microbiological quality and safety of marinated pork steaks in
46 Germany. Producers have to comply with the rules of Reg. (EC) No. 2073/2005. Additionally,
47 the German Society for Hygiene and Microbiology (DGHM) has published indicative and
48 warning values for several food categories, in particular for raw and unseasoned pork
49 (DGHM, 2013). These criteria have to be regarded as recommendations based on scientific
50 studies, observations by food control authorities and standards of food industry. It cannot be
51 ascertained whether the recommendations of the DGHM are transferable to marinated pork
52 products, where an introduction of pathogens might also occur via marinades. Producers of
53 marinated pork steaks assign different values for minimum shelf life to similar products,
54 which further complicates an assessment of product safety.

55 The aim of our work was to evaluate the microbiological quality and safety of marinated pork
56 products. Therefore, we analyzed vacuum packed, marinated pork neck steaks from German
57 retail for microbiological parameters and foodborne pathogens. To assess the impact of
58 marinades on the microbiological safety of the steaks, marinades used for the production of
59 marinated pork steaks were also investigated.

60 **2. Material and methods**

61 **2.1 Sampling**

62 Meat samples: A total of 300 vacuum-packed, marinated pork steak-products were
63 purchased in two periods from self-service counters of retail stores in Bavaria, Germany: 150
64 samples from June to October 2008 and 150 samples from March to June 2009. Samples
65 originated from 13 different producers (Table 1). Producers and product categories were
66 identical in the two sampling periods. Due to the wide variety of marinated pork steaks
67 offered in the German retail, samples were classified - based on the main type of flavor or
68 seasonings - as products with mustard-/beer-marinade, paprika-marinade and herbs-/garlic-
69 marinade according to Frey (1999). Dispersions on water-oil-basis with thickening
70 ingredients were classified as mustard/beer-marinades. Paprika-marinades contained pure
71 seasoning oils, emulsion- or dispersion-marinades or mixtures. Oil-spices-mixtures without
72 water were categorized as herbs-/garlic marinades. One hundred products were sampled
73 from each category during sampling periods. Two pork steaks with equal minimum shelf life
74 were purchased from the same producer at different days. After collection, samples were
75 transported to the laboratory under cooling conditions and stored at 4 °C. Microbiological

76 analyses were carried out 3 days after purchase and at the end of minimum shelf life (+/- 1
77 day).

78 Marinades: Thirty marinades were delivered by five different producers from spice industry in
79 customary packing during August 2008 and August 2009 and stored at 4 °C until analyses.
80 The marinades, commonly used for production of marinated pork steaks in Germany, were
81 also classified into the three categories mustard-/beer-marinades, paprika-marinades and
82 herbs-/garlic-marinade as described above (Table 1).

83

84 **2.2. Physicochemical and microbiological analyses of marinated pork samples and** 85 **marinades**

86
87 Analyses were carried out on the basis of the German official collection of methods
88 according to § 64 of German Food and Feed Legislation (LFGB, 2013). Each sample was
89 tested twice.

90 Measurement of pH-value and water activity: pH-values were measured in the cores of the
91 steaks or in marinades (pH 537, WTW, Weilheim, Germany). Water activity measurements of
92 marinades were done at 25 °C using Novasina a_w Sprint TH 500 (Axair Ltd., Switzerland)

93 Microbiological analyses: For detection and enumeration of aerobic mesophilic bacteria,
94 *Enterobacteriaceae*, coagulase+ staphylococci, *Bacillus cereus*, sulfite reducing clostridia
95 and *Listeria monocytogenes*, 20 grams of steaks or marinades were weighed into sterile
96 stomacher bags. After homogenization for 2 min in 180 ml sterile physiological sodium
97 chloride solution (0.85% NaCl) in a Coolworth Stomacher 400 (Seward, England) and serial
98 dilution in sterile physiological sodium chloride solution (method L.06.00-16; LFGB, 2013),
99 samples were plated onto appropriate agars and incubated as shown in Table 2.

100 For testing the presence of *Salmonella* spp. and Shiga toxin producing *E. coli* 25 g of the
101 samples were enriched in an appropriate selective enrichment broth (Table 2).

102

103 Identification and further characterization of isolated pathogen strains were performed by
104 biochemical, molecular biological and/or immunological methods as listed in Table 3.

105 Sample preparation for PCR assays of enriched samples were done according to De Medici
106 et al. (2003). Briefly, 1 mL of sample enrichments were centrifuged at 10,000 g for 5 min,
107 supernatant was discarded and the sediment was resuspended in phosphate buffered saline
108 (PBS) (pH 7.4) and centrifuged again at 10,000 g for 5 min. This procedure was repeated
109 two times. The pellet was resuspended in 300 µL PBS, heated at 100 °C in a thermoblock
110 (Eppendorf AG, Germany) for 10 min, immediately cooled on ice and centrifuged for 1 min at
111 10,000 g. The supernatant was used as PCR template.

112 For strain confirmation, single colonies were taken from the respective agars, re-suspended
113 in 500 μ L PBS, heated for 10 min at 100 $^{\circ}$ C and centrifuged at 10,000 g for 1 min.
114 Supernatants were used for the PCR assays.

115

116 **2.3 Statistical Analyses**

117 Median, mean values and standard deviations were calculated by Microsoft Excel 2010. Box
118 plot diagrams were compiled by Statistica $\text{\textcircled{R}}$ version 7.1.

119

120 **3. Results and discussion**

121

122 **3.1 Marinated pork steaks**

123 This study presents data on microbiological quality and safety of marinated pork steaks from
124 self service areas of local German supermarkets from two sampling periods. Varieties and
125 number of samples from 13 German producers were equal for the two sampling periods
126 (Table 1, Figure 1). Therefore, a direct comparison of the data and an estimation of potential
127 seasonal effects can be derived. Because of large product diversity, steak samples were
128 divided into categories of products with mustard-/beer-marinade, paprika- or herbs-/garlic-
129 marinade based on their main flavors, according to Frey (1999).

130 Until the end of minimum shelf life at 4 $^{\circ}$ C, pH-values of marinated pork steaks decreased by
131 about 0.45 units. Concurrently, aerobic plate counts rose by about 1 to 2 log during minimum
132 storage life to values up to 8 or 9 log cfu g^{-1} (Figure 1). Plate counts correlated with numbers
133 of lactic acid bacteria, which were analyzed in the second sampling period (Table 4). Our
134 results is consistent with report of Schirmer et al. (2009). As in fresh packed meat, lactic acid
135 bacteria developed in marinated pork products to the dominant bacterial population after 3 -
136 4 weeks of cold storage with cell counts up to 8 log cfu g^{-1} . This resulted in lowered pH-
137 values and increased aerobic mesophilic plate counts (Blixt & Borch, 2002; Holley et al.,
138 2004). Aerobic plate counts in meat products higher than log 6 cfu g^{-1} are often accompanied
139 by first signs of spoilage (Blixt & Borch, 2002; Holley et al., 2004). Therefore, our findings at
140 the second examination time suggest that possible spoilage indications may be obscured by
141 marinades.

142 We did not observe significant differences between the results of the two sampling periods
143 (Figure 1). Consequently, no noticeable seasonal effects of varying climatic conditions or
144 different consumer demands were observed. This might be an indication of consistent
145 conditions during production and distribution of marinated pork steaks, e.g. adequate cooling
146 temperatures.

147 According to Holley et al. (2004), *Enterobacteriaceae* present on stored vacuum-packed pork
148 are useful indicators of efficacy of plant sanitation. Although *Enterobacteriaceae* occurred in
149 most steak samples (Table 4), the proportion of *Enterobacteriaceae* was in the most samples
150 of our study (266/300) below 5 % of the microbiological population. Generally, this could be
151 considered as a reflection of acceptable sanitation practice and hygiene (Holley et al., 2004).
152 However, in 11 % of the samples (34/300) *Enterobacteriaceae* counts of more than $\log 5 \text{ cfu}$
153 g^{-1} were found (Table 4). These steak samples originated from 12 producers (data not
154 shown). In one product with paprika marinade, 8 products with mustard marinade and 20
155 samples with herbs-/garlic marinade the proportion of *Enterobacteriaceae* was more than 5
156 % of the total bacterial population (Table 4). In Germany, marinated pork neck steaks are
157 produced usually from frozen pork necks. Therefore, producers should verify their incoming
158 quality control of the raw meat.

159 *Salmonella* were detected only during the second sampling period in 2 % of the steaks
160 (Table 4). These results are in accordance with recent studies, which reported a presence of
161 *Salmonella* spp. in pork within 2 and 6 % of samples (Rabsch et al 2013; Hauser et al. 2010;
162 Meyer et al., 2010; Prendergast et al., 2008). *Salmonella* positive steak samples were not
163 related to those with high *Enterobacteriaceae* counts ($> 5 \log \text{ cfu g}^{-1}$).

164 Serotyping of *Salmonella* isolates resulted in serotype Typhimurium (Table 5), which is one
165 of the most common serotypes in pork products (Friedrich et al., 2010). Our analyses
166 showed persistence of this serotype in 6 steaks with paprika marinades (Table 4). These
167 products originated from the same producer and isolates were classified as monophasic
168 variants of the serotype O4,12 phage type DT 193 and biphasic variants of the serotype O
169 4,5,12 phage type DT 120 (Table 5). Therefore, *Salmonella* could survive in these products
170 over a period of 18 days at 4 °C.

171 One steak contained STEC, and further differentiation resulted in serotype ONT:H19 and
172 virulence factor Stx2e (Table 5). STEC producing Stx2e are associated with edema disease
173 in pigs. *stx2e*-positive STEC-isolates were frequently detected in pork with percentage of
174 more than 50 (Beutin et al., 2007), but not in patients with severe STEC-caused diseases
175 (Beutin et al., 2008). Only mild diarrhea was described after STEC-infection with Shigatoxin
176 2e-producing STEC (Friedrich et al., 2002). Therefore, marinated pork steaks might not to be
177 a common source for highly pathogenic EHEC strains.

178 *L. monocytogenes* were detected in 5 meat samples (1.7 %) with herbs-/garlic-marinade with
179 counts ranging within 1 and 2 $\log \text{ cfu g}^{-1}$. Earlier studies documented an occurrence of
180 *L. monocytogenes* in pork within 1 and 36 % (Yeh et al., 2005; Netschajew et al., 2009). In
181 our analyses *L. monocytogenes* were mainly isolated at the end of shelf life (after 18 d

182 storage at 4 °C). Consequently, this pathogen survived in marinated pork samples. Most of
183 the isolates belonged to serotype 1/2a (Table 5), which is detected commonly in pork
184 products (Hellstrom et al., 2010). The other detected serotype 1/2c can often be found in
185 food of animal origin and therefore sometimes in meat products (Hong et al., 2007).

186 Eight percent of the pork samples were positive for *St. aureus* with counts up to 2.53 log
187 cfu g⁻¹. Cell numbers at the date of purchase were similar to those at end of shelf life (Table
188 4). Therefore, no growth of *St. aureus* was observed in marinated pork steaks. For a food
189 borne intoxication with *Staphylococcus* enterotoxins, an amount of 0.1 to 1 µg per kg body
190 weight is necessary. A production of toxic dose demands *St. aureus* counts of more than 4
191 log cfu g⁻¹ (Hennekinne et al., 2010). Therefore, there should be no impact for consumer's
192 health, when the marinated pork steaks were stored before consumption at adequate cooling
193 conditions.

194 Analysis of *St. aureus* strains for SE-production showed enterotoxin production in 65 % of
195 the strains (Table 5), which is slightly more than documented by other studies. They showed
196 a prevalence of SE producing *St. aureus* in food of about 40 - 51 % and of about 35 - 60 % in
197 raw meat (Atanassova et al., 2001; Normanno et al., 2007; Nitzsche et al., 2007; Pereira et
198 al., 2009). The most common SE-type in our assays was SED (59 %), followed by SEC
199 (50 %) and SEA (45 %). These 3 toxin types occurred most frequently together in our *St.*
200 *aureus* strains (Table 5). Our data are in accordance with results of Normanno et al. (2007).
201 They detected SED (33.6 %) as the most frequent enterotoxin type in milk and meat
202 products, followed by SEA (18.4 %) and SEC (15.2 %). Conversely, Pereira et al. (2009)
203 described SEA as the most frequent enterotoxin in raw meat and fermented meat products.
204 The difference to our data may be based on different methods, because we analyzed our *St.*
205 *aureus* strains for toxin production by ELISA whereas Pereira et al. (2009) analysed for
206 genes encoding toxin production by molecular methods. In general, numbers of positive
207 molecular biological results are higher than those for real toxin formation (Najera-Sanchez et
208 al., 2003).

209 One *St. aureus* strain was MRSA positive (Table 5). This is in accordance with other studies,
210 which showed MRSA occurrence in pork in 0.3 – 10.7 % of the samples (De Boer et al.,
211 2009; Lim et al., 2010).

212 *Bacillus cereus* were isolated from 64 samples (21 %) of marinated pork steaks. Highest
213 contamination rates were found in samples with herbs-/garlic-marinade, (< 3 log cfu g⁻¹,
214 Table 4). For toxigenic *B. cereus* to cause implications for public health, an interruption of
215 cold chain would be necessary with subsequent growth to numbers of up to log 5 - 6 cfu g⁻¹
216 (Ehling-Schulz et al., 2004b). Marinated steaks are usually cooked thoroughly before

217 consumption, which leads to inactivation of toxins of the diarrhea enterotoxin complex. A
218 higher risk for consumer's health would exist, if *B. cereus* strains harbored the ability to form
219 heat stable emetic toxin (Rajkovic et al., 2008). Our isolates possessed no genes for
220 cereulide formation (Table 5). In food, an occurrence of cereulide forming *B. cereus* strains is
221 likely within 0 -13 % of the samples (Schulz, 2004; Altayar & Sutherland, 2006; Kreuzberger
222 et al., 2008; Rau et al., 2009). Our results may be based on higher temperature optima of
223 emetic *B. cereus* strains compared with non-emetic isolates, since emetic *B. cereus* strains
224 cannot grow and produce cereulide at temperatures below 10 °C (Carlin et al., 2006).
225 About 98 % of analyzed *B. cereus* isolates possessed genes coding for diarrhoea toxin
226 complex (Table 5). Kreuzberger et al. (2008) also detected genes encoding this toxin
227 complex in 99 % of *B. cereus* strains. Most of our isolates (95.3 %) harbored the three genes
228 of the NhE-complex (Table 5). Similar results were found in other studies (Guinebretriere et
229 al., 2002; Moravek et al., 2006; Molva et al., 2009). Remarkably, all isolates with all
230 components of HBL-complex possessed also three gene components of NhE-complex
231 (Table 5). Therefore, these *B. cereus* isolates have the potential for production of both toxin
232 components with maximal biologic activity (Hansen & Hendrikson, 2001).

233

234 3.2 Marinades

235 In the 30 analyzed marinades, usually used for production of marinated pork steaks, lower
236 pH-values and plate counts were determined than in marinated steaks (Figure 1). In addition,
237 ranges of pH-values were larger in pure marinades than in marinated pork samples. These
238 results clearly demonstrate the buffering capacity of meat. This fact might allow survival of
239 bacteria as shown by our microbiological analyses: *Enterobacteriaceae* were detected in 92
240 % of marinated meat samples but only in 6.7 % of the marinades and *Enterobacteriaceae*
241 counts increased until the end of shelf life of marinated pork samples. This might also
242 indicate that contamination with *Enterobacteriaceae* occurred during meat processing rather
243 than by addition of marinades.

244 According to our results, marinades with low pH-values seemed to have higher bactericidal
245 effects than marinades with high oil content and low water activity.

246 Microbiological analyses of marinades resulted in negative findings for *Salmonella* spp.,
247 STEC, *L. monocytogenes* and *St. aureus* (Table 4). Spices and herbs, which were used for
248 production of marinades, might contain pathogens (e.g. *Salmonella* spp.), but antimicrobial
249 substances in spices and herbs such as in garlic, onions or clove, are able to inhibit bacterial
250 growth (Graubaum et al., 2005). This, in combination with low pH- and low water activity-
251 values of marinades might explain negative results of vegetative pathogens in marinades.

252 Marinades contained spore forming bacteria such as *B. cereus* and sulfite reducing clostridia
253 up to 2.36 log cfu g⁻¹ (Table 4). Molecular biological analyses of isolates from marinades for
254 gene components of diarrhoea and emetic toxin complex showed results similar to analyses
255 of isolates from marinated pork steaks. Entry of toxigenic *B. cereus* into marinated pork
256 products therefore appears to occur via marinades, particularly by herbs and spices (Little et
257 al., 2003; Psomas et al., 2009). For information about genotypic relationships within *B.*
258 *cereus* isolates from steaks and marinades, further investigations are necessary, e.g.
259 random amplification of polymorphic DNA (RAPD) or multi-locus sequence typing (MLST)
260 (Ehling-Schulz et al., 2005; Guinebretiere et al., 2008).

261

262 **Conclusions**

263 Our data demonstrate the occurrence of food borne infectious bacteria in marinated meat
264 products. Marinating could not eliminate pathogens in pork steaks during shelf life period.
265 However, the risk for consumer's health should be negligible, when the steaks are properly
266 stored and prepared before consumption.

267 Based on the results of our work, the microbiological criteria of Reg. (EC) No. 2073/2005 and
268 the recommendations of the DGHM (2013) the indicative and warning values for raw pork are
269 transferable for pre-packed marinated pork neck steaks until the end of shelf life.

Table 3: Methods for confirmation and characterization of isolates of foodborne pathogens in vacuum packed marinated pork neck steaks.

Pathogen	Method	Reference
<i>Salmonella</i> spp.	<i>invA</i> -gene-detection	(Rahn et al., 1992)
	Serotyping/ phage typing	(Rabsch, 2007)
<i>L. monocytogenes</i>	rhamnose-/xylose fermentation hemolysis	(Groves et al., 1977)
	serotyping (multiplex-PCR)	(Doumith et al., 2004)
<i>B. cereus</i>	<i>gyrB</i> -gene-detection	(Yamada et al., 1999)
	Detection of toxigenicity	
	Emetic toxin	<i>cesB</i> (Ehling-Schulz et al., 2004a and 2006)
	cereulid	
	Diarrhetic toxin	<i>hblA</i> (Mäntynen et al., 1998)
		<i>hblC</i> (Moravek et al., 2004)
STEC		<i>hblD</i> (Ryan et al., 1997)
		<i>nheA</i> (Moravek et al., 2004)
		<i>nheBC</i> (Dietrich et al., 2005)
	<i>stx1</i>	(Rüssmann et al., 1995)
	<i>stx2</i>	(Cebula et al., 1995)
	<i>eae</i>	(Schmidt et al., 1993)
<i>St. aureus</i>	<i>hlyA</i>	(Schmidt et al., 1995)
	Serotyping and subtypes of <i>stx2</i>	(Beutin et al., 2007)
	Latexagglutination-assay	(Zschöck et al., 2005)
	Assay for enterotoxins (ELISA)	(Park et al., 1996)
	MRSA-screening (Cefoxitin-agar diffusion assay)	(Boubaker et al., 2004)
	(confirmation of MRSA by PCR)	(Mehrotra et al., 2000)

1 **Table 4:** Microbiological parameters of vacuum packed marinated pork steaks from self service areas of German retail (n=300). Cat.: Steak
2 samples were categorized into three groups. M = products with mustard-/beer-marinade (n=100), P = products with paprika-marinade (n=100), H =
3 products with herbs/garlic-marinade (n=100). Steak samples were purchased during two sampling periods in 2008 and 2009 and analyzed at date
4 of purchase (I) and the end of dedicated minimum shelf life (II). PC = aerobic mesophilic plate count; LAB = counts of lactic acid bacteria. n =
5 number of positive samples, N = number of analyzed steak samples. ↑: Increase of bacterial counts $\geq 1 \log \text{cfu g}^{-1}$ and percentage $>10 \%$; →: no
6 change of cell counts ($< 1 \log \text{cfu g}^{-1}$ and $<10 \%$); ↓: Reduction of cell counts $\geq 1 \log \text{cfu g}^{-1}$ and percentage of positive samples $>10 \%$; * Results
7 were rounded to one decimal place. ** qualitative detection after sample enrichment; n.a. = not applicable; - = not detected.

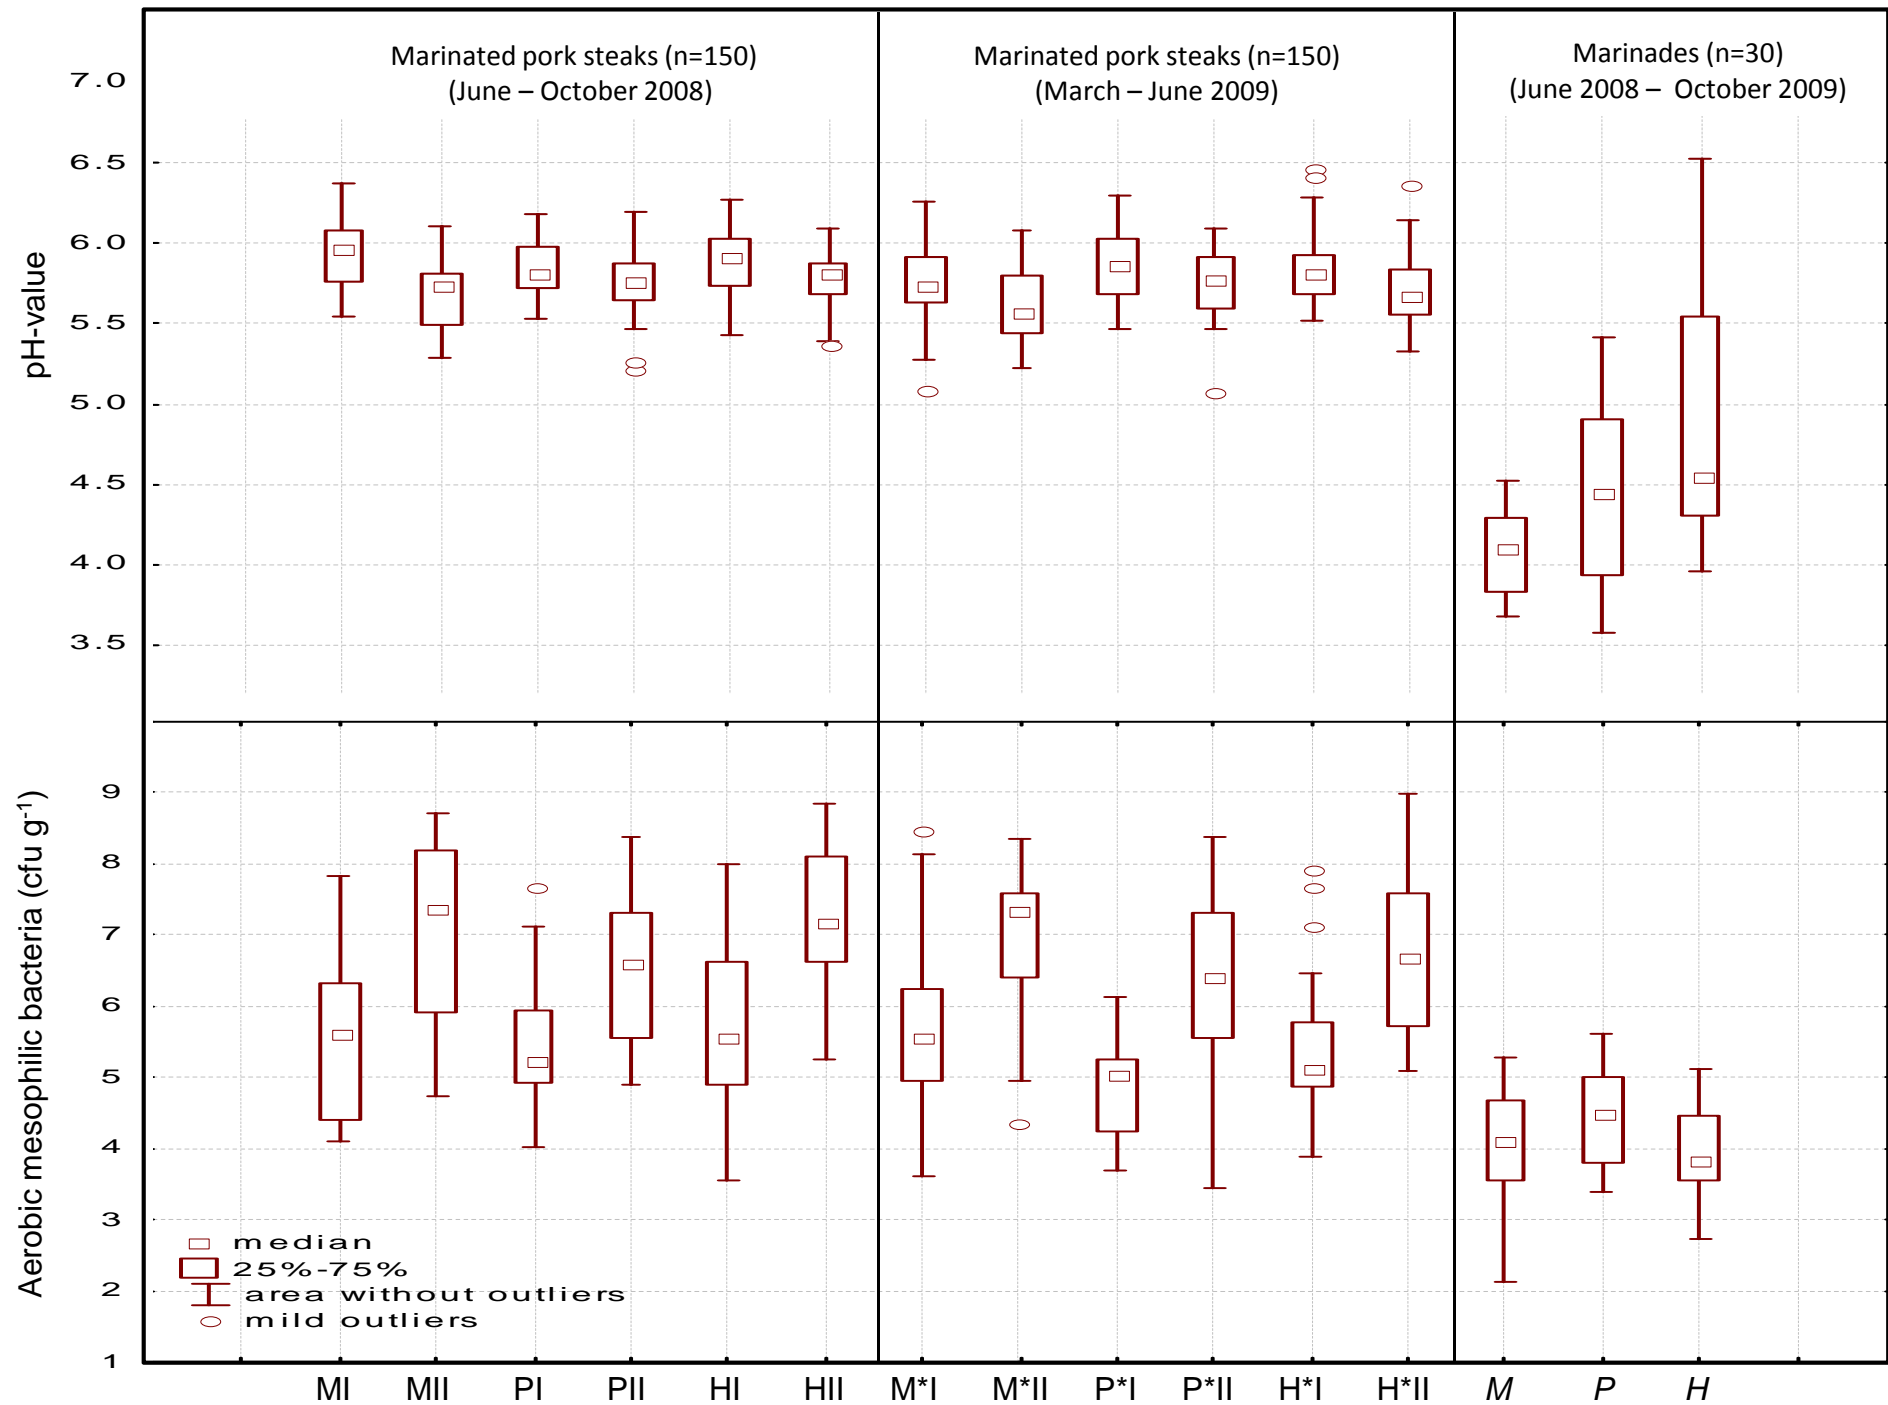

Cat.	Target	Microbiological results at date of purchase (I)											Microbiological results at the end of minimum shelf life (II)											trend

Figure 1: Box-plot of pH-values and aerobic mesophilic plate counts (PC) of vacuum packed marinated pork steaks from self service areas of German retail and of marinades from German producers. Steak samples were categorized into three groups. M = products with mustard-/beer-marinade, P = products with paprika-marinades, H = products with herbs-marinades. M I, P I, H I: 25 samples were analyzed 3 days after purchasing for each category. M II, P II, H II: Analyses of 25 steak samples at the end of dedicated minimum shelf life for each category. * Steak samples were purchased and analyzed in 2009. *M, P, H:* Mustard-, paprika-, or herbs-/garlic-marinades, samples were analyzed between June 2008 and October 2009.

Highlights

We analyzed 300 marinated pork steaks at beginning and end of shelf life.
Additionally 30 marinades, used for production of steaks were analyzed.
Food pathogens were detected in the steaks in a range from 0 to 21%.
Marinades with low pH-values showed higher bactericidal effects.
