Barley yellow dwarf virus (BYDV) causes high yield losses worldwide. Thereby aphids play an important role as virus vectors. Such yield losses caused by BYDV may be reduced using virus-tolerance genes from primary genepool of barley. Additionally, complete resistance to the virus has been introgressed via interspecific crosses from the secondary genepool within the tetraploid wild species Hordeum bulbosum to barley chromosome 3HL. Previous studies indicate that this resistance is governed by a dominant

gene,  $Ryd4^{Hb}$ . In the present study, a BC<sub>2</sub>F<sub>4</sub> mapping population consisting of 134 individuals was used to establish a molecular-marker map for  $Ryd4^{Hb}$ . Using the model genome of  $Oryza\ sativa$ , the Massive Analysis of cDNA Ends (MACE) approach was applied to develop novel markers. One of these markers cosegregated with  $Ryd4^{Hb}$ . For a fine-mapping of  $Ryd4^{Hb}$  a BC<sub>2</sub>F<sub>6</sub> family of 454 individuals will be used.
