Introduction

Variability in leaf density leads to differences in the penetration of canopies.

Leaf density of apple trees varying considerably

The existing differences in leaf density causing disparities in deposits

Deposit on the backside of the tree – seen from the sprayer – is additional and can be saved

Method and results

Measuring all parameters which influence the penetration and measurement of the deposit in front, middle and on the backside of the tree will lead to a data pool.

Array arrangement for measuring the deposit inside and outside trees. (about 300 experiments)

Parameters for parameters list		
Group	Parameter	Parameter unit
Density of leaves	Density of leaves	kg/m³
	Depth of the canopy	m
	Leaf area index	m²/m²
	Leaf area index	m²/m²
Penetration of the spray	Wind speed	m/s
	Wind direction	°
Sprayer parameters	Flow rate	l/min
	Pressure	bar
Tree parameters	Tree height	m
	Tree diameter	cm

Measurement parameters for	
Tree	Sprayer
Depth of the canopy	Flow rate of the sprayer
Wind speed and direction	Pressure
Tree height	Tree diameter

Results of the multiple regression analysis between the parameters possibly taking an influence and parameters and deposit treatment:

- Parameters actually taking an influence
- An equation to describe the deposit on the backside of the tree.

Usage

Multiple regression analysis of the data pool delivers a model to calculate PPP saved.

Example for calculating the reduction of PPP.

Two possible ways of how to use results.

An example of a handout specific for the sprayer used. The colors of the frames show the reduction of PPP.
